**IMPORTANT:** Provide all supporting documentation that this water body is important for the spawning, rearing or migration of anadromous fish, including: number of fish and life stages observed; sampling methods, sampling duration and area sampled; copies of field notes; etc. Attach a copy of a map showing location of mouth and observed upper extent of each species, as well as other information such as: specific stream reaches observed as spawning or rearing habitat; locations, types, and heights of any barriers; etc.

Comments:

Fish sampling of the ADOT/PF mine site began in 1998 the first year after the site was flooded (Fall 1997) for rehabilitation. Anadromous species were captured (fyke-nets) using the site during the first full open-water season in 1998. Dolly Varden were first identified using the site followed by anadromous broad whitefish and least cisco in subsequent years. Dolly Varden also were captured just upstream of the mine site, just down stream of a connected wetland complex. Resident fish species were also captured immediately after flooding (Arctic grayling, round whitefish, slimy sculpin and ninespine stickleback). Copies of Trip Reports from 1998, 1999 and field data from 2000 are attached.

ADDED INTO 2000 THIS IS DUPLICATE + MORE INFO.

## **ADOT/PF Deadhorse Mine Site Fish and Water Quality Monitoring, 1999.**

By: William Morris

### **Introduction:**

In 1997 a gravel mine site operated by the Alaska Department of Transportation and Public Facilities (ADOT/PF) was flooded as part of the site rehabilitation plan. The mine site was connected to a tundra stream draining a large wetland complex. The stream runs from the mine site to the Sagavanirktok River about 0.75 Km downstream. The pit was designed to create fish over-wintering habitat, and to provide a shallow bench around the margins of the pit for aquatic vegetation to take root and provide habitat for fish food organisms, once rehabilitated. The pit first flooded in August 1997 and fish and water quality sampling was first conducted during the open-water season, 1998. With the proximity to the Sagavanirktok River fish moved into the site almost immediately. In 1998, Arctic grayling (*Thymallus arcticus*), Dolly Varden (*Salvelinus malma*), round whitefish (*Prosopium cylindraceum*), slimy sculpin (*Cottus cognatus*), and ninespine stickleback (*Pungitius pungitius*) were captured in the pit and pit inlet (Hemming and Morris 1998). Arctic grayling captured were primarily young-of-the-year fish indicating Arctic grayling are using the upstream wetlands for spawning (Hemming and Morris 1998).

Rehabilitation work on the pit will continue during winter 1999/2000 when overburden piles on the pit margins will be removed by either moving the piles onto the ice and, thus, redistributing the material into the pit during break-up 2000, or complete removal and reuse. Fish and water quality monitoring will continue in 2000 to monitor for any potential effects of the overburden addition to the pit. Impacts should be minimal and virtually undetectable by fall 2000. This report summarizes fish and water quality sampling conducted during summer 1999.

### **Methods:**

Fish sampling was conducted twice during the 1999 open-water season, once in late June and once in late August. Fish sampling gear consisted of 3.7 m long fyke-nets with two 0.9 m entrance frames, five hoops, a 1.8 m cod end (fish collection/holding area), and two 0.9 X 7.6 m wings attached to the sides of the first entrance frame. Nets were set from shore with a 15.2 m lead net designed to funnel fish into the fyke-net. Nets were set and checked at 24-hour intervals for up to four days. All fish captured were identified and measured to fork length (FL) in mm and released on site. Ninespine stickleback were counted and released with no length measurement. During June sampling, net sites were accessed with a PolarCraft™ riverboat.

Water quality sampling was conducted in late June upstream of the pit inlet and in the gravel mine site. A PolarCraft™ riverboat was used to access both sites and used as a work platform to collect water quality data. A Hydrolab® Minisonde® water quality

probe connected to a Surveyor 4<sup>®</sup> digital computer display unit was used to measure temperature (C°), dissolved oxygen (mg/L), percent dissolved oxygen saturation, conductivity (uS), and pH. Measurements were taken at one-meter intervals from just below the surface to the bottom of the pit.

### Results:

A total of 41 fish (not including ninespine stickleback) were captured during summer 1999 sampling. Six species of fish were captured including, Arctic grayling, round whitefish, ninespine stickleback, Dolly Varden, least cisco (*Coregonus sardinella*), and broad whitefish (*Coregonus nasus*). Arctic grayling were the most numerous species captured (33 fish), representing 80% of the overall catch (Table 1). Species composition in the pit was similar to 1998 results, however; least cisco and broad whitefish were not found in 1998 and slimy sculpin were absent in 1999. Additionally, no young-of-the-year Arctic grayling were captured in 1999.

Table 1. Fish sampling results from the ADOT/PF Deadhorse Mine Site, 1999.

| Sampling Period | Species measured to Fork Length (mm). |                 |             |                 |                       |              |
|-----------------|---------------------------------------|-----------------|-------------|-----------------|-----------------------|--------------|

Water quality results indicate that the pit is well mixed, high in dissolved oxygen, basic, and filled with fresh water (Table 2). The inlet channel has similar water chemistry with slightly higher temperatures (in June) (Table 2). Water quality indicates the pit and inlet are suitable for fish survival and pit depth (7.5 m at sample site) is more than adequate to overwinter large numbers of fish.

**Table 2. ADOT/PF Deadhorse Mine Site water quality monitoring, June 1999.**

### **Discussion:**

Fish colonization and use of the Deadhorse mine site has been extremely rapid. The pit has been flooded for two full open-water seasons, and already, most freshwater resident and anadromous species that use freshwater habitats have been documented using the pit. Ninespine stickleback and Dolly Varden were the first species documented using the pit in June 1998. By August 1998 Arctic grayling, round whitefish, and slimy sculpin were identified in the pit. By August 1999 both least cisco and broad whitefish were documented in the pit as well. At this point seven species have been documented using the pit, including 4 freshwater species (round whitefish, Arctic grayling, ninespine stickleback, and slimy sculpin), and 3 anadromous species (least cisco, broad whitefish, and Dolly Varden). The proximity of the mine site to the Sagavanirktok River, one of the most productive fish systems in the Prudhoe Bay area, is undoubtedly aiding in the rapid use of the pit by fish.

In 1998 many young-of-the-year Arctic grayling were identified in the inlet stream and the pit itself, indicating Arctic grayling spawning may have occurred in the upstream wetland complex. However, 1999 sampling failed to show the presence of young-of-the-year Arctic grayling, this finding is consistent with low recruitment seen in other North

Slope gravel pits this year. Some Arctic grayling captured in 1999 were in the 1+ age class and may represent fish spawned from the system last year (fish with fork length 90-110 mm). This indicates that some Arctic grayling probably are overwintering in the pit.

Monitoring of fish use and water quality will continue in summer 2000. 2000 monitoring will allow us to keep track of changes in fish use, such as additional species using the pit for spawning, and water quality. This is especially important as pit remediation measures to be conducted this winter could have some minor effects on pit water quality. Overburden moved back onto the pit should be redistributed quickly during break-up and should settle out by fall. There is some potential for changes in fish use based on increased turbidity; however, even if this is the case the impact should be limited to 2000.

## **ADOT Deadhorse Mine Site**

### **Fish and Water Quality Monitoring Report, August 24-26, 1998**

**By : Carl Hemming and William Morris**

#### **Introduction**

In 1997, a gravel mine site was opened to provide construction materials for Deadhorse Airport improvements. The site is located west of the Dalton Highway approximately 2 miles south of Deadhorse. In a cooperative planning effort involving the Alaska Department of Transportation (ADOT), Fish and Game, Natural Resources, and federal resource agencies, a site design and rehabilitation plan was developed. The plan followed the guidance provided in ADF&G Technical Report 93-3, "North Slope Gravel Pit Performance Guidelines" (McLean 1993). It was determined during the planning phase that the site would be closed out and rehabilitated after gravel removal for the airport project was complete. Long term goals were freshwater for road maintenance and deep water habitat for wintering fish. Site design features for fish included an outlet connection to a tundra stream that joins the Sagavanirktok River, and shallow water zones around the perimeter of the site. The outlet connection was designed to allow fish to access the site using the existing stream channel and the shallow water zones were designed to foster colonization by aquatic plants and to increase production of fish food organisms.

Site restoration was completed in late summer 1997, and flooding occurred rapidly aided by heavy rainfall. This report describes monitoring of fish colonization and water quality in the mine site during 1998, the first full season after site restoration and flooding. This is the second report on this project and includes data collected between August 24 and 26, 1998.

#### **Methods**

We fished fyke nets at two locations between August 24 and 26. A net was fished in shallow water on the south side of the pit at a point midway between the access ramp and the inlet channel and a second net was fished in the inlet channel. The net at on the south side of the site was larger with two 1.2 m (4 ft) square entrance frames, five hoops, a 1.8 m (6 ft) cod end, and 7.6 m (25 ft) net wings attached to the entrance frames. The net fished in the inlet channel was similar but smaller with two 0.9 m (3 ft) entrance frames and a 15.2 m (50 ft) center lead attached to the entrance frame and to shore. The species of each fish captured was determined, the fork length was measured to the nearest millimeter, and the fish was released at the capture site. Ninespine stickleback (*Pungitius pungitius*) were identified, enumerated, and released without length measurement. When large catches of fish in the same size class occurred a subsample was measured and the remainder were enumerated and released.

A water quality sampling station was selected in the deepest area of gravel excavation at the southwest end of the reservoir. We used a aluminum riverboat with an antiquated sputtering outboard motor for access, anchored in the deep area, and used the boat as a work platform. Water measurements were taken at the surface and at one meter intervals through the water column to the bottom. Water measurements were taken with a Hydrolab®, MiniSonde®, water quality multiprobe connected by a cable to a Surveyor® 4 water quality data display unit. Parameters measured included temperature ° C, dissolved oxygen concentration (mg/l), dissolved oxygen percent saturation (temperature and barometrically corrected), pH, salinity, and depth (measured with cable calibrations). The meter was calibrated to suggested specification prior to use in the field and rechecked after sampling was completed. The dissolved oxygen concentration was calibrated using the Winkler Titration method (average of three measurements) and pH and conductivity were calibrated with standard solutions.

## Results

### Fish Sampling

We captured ninespine stickleback, Dolly Varden (*Salvelinus malma*), Arctic grayling (*Thymallus arcticus*), round whitefish (*Prosopium cylindraceum*), and slimy sculpin (*Cottus cognatus*) (Table 1).

Table 1. Results of fyke net fish sampling at ADOT Deadhorse Gravel Site, August 24-26, 1998.

| Date      | Net Location | Fish Species          | Number |
|-----------|--------------|-----------------------|--------|
| August 25 | South side   | Arctic grayling       | 46     |
|           |              | Dolly Varden          | 3      |

|           |              | Arctic grayling       | 14     |
|           |              | Ninespine stickleback | 572    |
|           |              | Slimy sculpin         | 1      |

## Water Quality

Water measurements were taken at 9 depth intervals from the surface to the bottom at 7.1 m (Table 2). The measurements indicate a well mixed waterbody as all parameters had uniform values through the water column.

Table 2. Water quality characteristics of ADOT Deadhorse Mine Site August 25, 1998.

| Depth (m)    | Temp ° C | D.O. Concentration<br>mg/l | D.O.<br>%<br>Saturation | Salinity<br>ppt | pH   |

## Discussion

The number of fish species captured in the ADOT Deadhorse pit increased from two in July to five in late August. Ninespine stickleback and Dolly Varden were found during both sample periods while Arctic grayling, slimy sculpin, and round whitefish were only captured in the late August sample period. The August catch included only one slimy sculpin and one round whitefish, while 154 Arctic grayling were captured. Eighty percent of the Arctic grayling were young-of-the-year (y-o-y) size class fish (Appendix I). We measured 70 of the y-o-y grayling and they ranged from 48 to 65 mm in length, with a mean of 54 mm (SD 3.1 mm).

The number of ninespine stickleback increased in August from that found in July. In July, stickleback abundance ranged from 12 to 97 per trap, while August catches ranged from 572 to 2288. The catch rate and size distribution of Dolly Varden was similar in each of the two sample periods. In July we captured 7 Dolly Varden ranging from 110 to 282 mm, with a mean length of 235 mm (SD 57), and in August we captured 6 Dolly Varden ranging from 145 to 284 mm, with a mean length of 213 mm (SD 49).

In August, the most important finding was the large numbers of y-o-y grayling (Figure 1). Grayling fry are generally found close to spawning sites. Large numbers of y-o-y grayling indicate that spawning occurs in the stream system that flows through the ADOT pit. This system includes an outlet channel between the pit and the Sag River and the

inlet to the ADOT pit that drains a large shallow lake complex west of the pit (Figure 2). While adult (>300 mm) grayling were not captured in either July or August it is possible that larger fish entered the stream shortly after the spring flood, spawned and moved downstream out of the system into the Sag river or moved upstream into the shallow wetland complex above the pit.

We conducted visual surveys of the outlet channel between the pit and the Sag River on June 16, August 5, and August 26. Fish were not observed in the outlet channel during these surveys. On June 16, the channel had continuous flow with one section between the pit outlet and the Dalton Highway having a one meter cascading drop. It appeared that access to the pit was not obstructed for fish moving upstream from the Sag River in mid June. On August 5 the outlet channel was dry at a point immediately downstream from the Dalton Highway culvert crossing, but continuous flow occurred between the pit and the culvert crossing. On August 26, the outlet channel was continuous between the pit and the Sag River but water depths of only 1 cm were found in the shallow riffle areas.

Water quality sampling in both July and August indicate that dissolved oxygen concentrations are at or near saturation at all depths though the water column. The deeper areas of the pit provide 5 to 7 meters of water suitable for wintering fish under 2 meters of ice cover.

The ADOT Deadhorse pit complex including the outlet channel to the Sag River and the inlet connection to extensive upstream wetlands provide high quality freshwater fish habitat. The outlet channel to the Sagavanirktok River is a pathway for colonization of the pit and shallow ponds upstream. This channel is used by at least 5 fish species. The upstream ponds provide a rich source of fish food organisms. The mine site contains deep well oxygenated waters suitable for wintering fish. The presence of y-o-y grayling indicate that stream habitats upstream or downstream of the ADOT pit were used by spawning grayling in the spring of 1998.

## **ADOT Deadhorse Mine Site**

### **Fish and Water Quality Monitoring Report**

**By : Carl Hemming and William Morris**

#### **Introduction**

In 1997, a gravel mine site was opened to provide construction materials for Deadhorse Airport improvements. The site is located west of the Dalton Highway approximately 2 miles south of Deadhorse. In a cooperative planning effort involving the Alaska Department of Transportation (ADOT), Fish and Game, Natural Resources, and federal resource agencies, a site design and rehabilitation plan was developed. The plan followed the guidance provided in ADF&G Technical Report 93-3, "North Slope Gravel Pit Performance Guidelines" (McLean 1993). It was determined during the planning phase that the site would be closed out and rehabilitated after gravel removal for the airport project was complete. Long term goals were freshwater for road maintenance and deep water habitat for wintering fish. Site design features for fish included an outlet connection to a tundra stream that joins the Sagavanirktok River, and shallow water zones around the perimeter of the site. The outlet connection was designed to allow fish to access the site using the existing stream channel and the shallow water zones were designed to foster colonization by aquatic plants and to increase production of fish food organisms.

Site restoration was completed in late summer 1997, and flooding occurred rapidly aided by heavy rainfall. This report describes monitoring of fish colonization and water quality in the mine site during 1998, the first full season after site restoration and flooding. This is the first report on this project and includes data collected in July, a second report will be prepared following August field work.

#### **Methods**

We fished fyke nets at two locations and live captured fish. A net was fished in the shallow water off the access ramp to the site from June 20 to June 22, and a second net was fished in the inlet channel from June 21 to 22. The net at the access ramp was larger with two 1.2 m (4 ft) square entrance frames, five hoops, a 1.8 m (6 ft) cod end, and 7.6 m (25 ft) net wings attached to the entrance frames. Approximately 10 m of center lead was deployed connecting the trap to shore. The net fished in the inlet channel was similar but smaller with two 0.9 m (3 ft) entrance frames and a 15.2 m (50 ft) center lead attached to the entrance frame and to shore. The species of each fish captured was determined, the fork length was measured to the nearest millimeter, and the fish was released at the capture site. Ninespine stickleback (*Pungitius pungitius*) were identified, enumerated, and released without length measurement.

A water quality sampling station was selected in the deepest area of gravel excavation at the southwest end of the reservoir. We used a Coleman Scanoe ® with a small outboard motor for access, anchored in the deep area, and used the Scanoe as a work platform. Water measurements were taken at the surface and at one meter intervals through the water column to the bottom. Water measurements were taken with a Hydrolab®, MiniSonde®, water quality multiprobe connected by a cable to a Surveyor® 4 water quality data display unit. Parameters measured included temperature ° C, dissolved oxygen concentration (mg/l), dissolved oxygen percent saturation (temperature and barometrically corrected), pH, salinity, and depth (measured with cable calibrations). The meter was calibrated to suggested specification prior to use in the field and rechecked after sampling was completed. The dissolved oxygen concentration was calibrated using the Winkler Titration method (average of three measurements) and pH and conductivity were calibrated with standard solutions.

## Results

### *Fish Sampling*

We captured ninespine stickleback and Dolly Varden (*Salvelinus malma*) at each of the two net sites (Table 1).

Table 1. Results of fyke net fish sampling at ADOT Deadhorse Gravel Site, July 20-22, 1998.

| Date    | Net Location  | Fish Species          | Number | Fork Length |
|---------|---------------|-----------------------|--------|-------------|
| July 21 | Access Ramp   | Dolly Varden          | 5      | 140         |
|         |               |                       |        | 194         |
|         |               |                       |        | 273         |
|         |               |                       |        | 279         |
|         |               |                       |        | 282         |
| July 22 |               | Ninespine stickleback | 12     | n/a         |
|         |               | Dolly Varden          | 1      | 241         |
|         |               | Ninespine stickleback | 15     | n/a         |
| July 22 | Inlet channel | Dolly Varden          | 1      | 110         |
|         |               | Ninespine stickleback | 97     | n/a         |

### *Water Quality*

Water measurements were made at 11 depth intervals from the surface to the bottom at 9.75 m (Table 2). The measurements indicate a well mixed waterbody as all parameters were fairly uniform through the water column with the exception of temperature and dissolved oxygen percent saturation which varied slightly near the bottom. Percent

saturation ranged from a high of 98% at the surface to 85.7 % near the bottom. The reservoir contains freshwater and the pH is basic.

Table 2. Water quality characteristics of ADOT Deadhorse Mine Site, July 21, 1998.

| Depth (m)     | Temp ° C | D.O.<br>Concentration<br>mg/l | D.O.<br>% Saturation | Salinity<br>ppt | pH   |
|---------------|----------|-------------------------------|----------------------|-----------------|------|
| Surface       | 12.65    | 10.45                         | 98.0                 | 0.14            | 8.59 |

## Discussion

Ninespine stickleback and Dolly Varden colonized the ADOT mine between late summer/fall 1997 when the site was flooded and July 21, 1998 when our fish sampling occurred. This time interval includes two open water periods during which fish could access the basin. The first in 1997 after the site was flooded following heavy rainfall events and the second after the spring breakup in 1998. On June 16, the stream channel connection to the Sag River was field checked and the armored pit outlet connection appeared to be functioning as designed to regulate outlet flow. The stream channel had continuous flow to the Sagavanirktok River providing fish with access to the site. The inlet channel had eroded upstream from the pit and was connected to extensive shallow lake habitat upstream of the reservoir. The reservoir was 20 % ice covered on June 16. On July 21 discharge in the stream channel was much reduced from that observed in June and less than a centimeter of water depth was present in sections of the stream channel. The Dolly Varden captured appeared in excellent condition, were robust, and had silvery coloration indicating they may have recently migrated from marine and nearshore habitats. The nets contained large numbers of eubranchiopods that were identified as tadpole shrimp. The tadpole shrimp may be providing a food resource for Dolly Varden in the pit. It is likely that these large freshwater invertebrates colonized the reservoir from shallow wetlands and ponds that are part of the drainage upstream of the ADOT mine site.

Conditions in the reservoir appear suitable for wintering fish populations. Dissolved oxygen concentrations are near saturation at all depths through the water column and the water depth is at least 9.75 m in the deepest portion of the basin. Assuming a maximum of 2 m ice cover, an estimated 7.75 m of well oxygenated water will remain under the ice for wintering fish. Two meters of ice closely approximates conditions measured at several similar freshwater sites in the area (Hemming 1993). The lower dissolved oxygen percent saturation values at 9 m and on the bottom result from a decrease in temperature at the bottom the reservoir. Frozen material close to the lake bottom may cool the deep water. Lower temperatures increase the oxygen holding capacity of the water and decrease the percent saturation values.

The shallow water zone at the perimeter of the lake and the extensive wetland pond complex upstream of the site will contribute to the production of freshwater invertebrates such as tadpole shrimp. These organisms may be used as food items for Dolly Varden and other fish that colonize the site over time.
